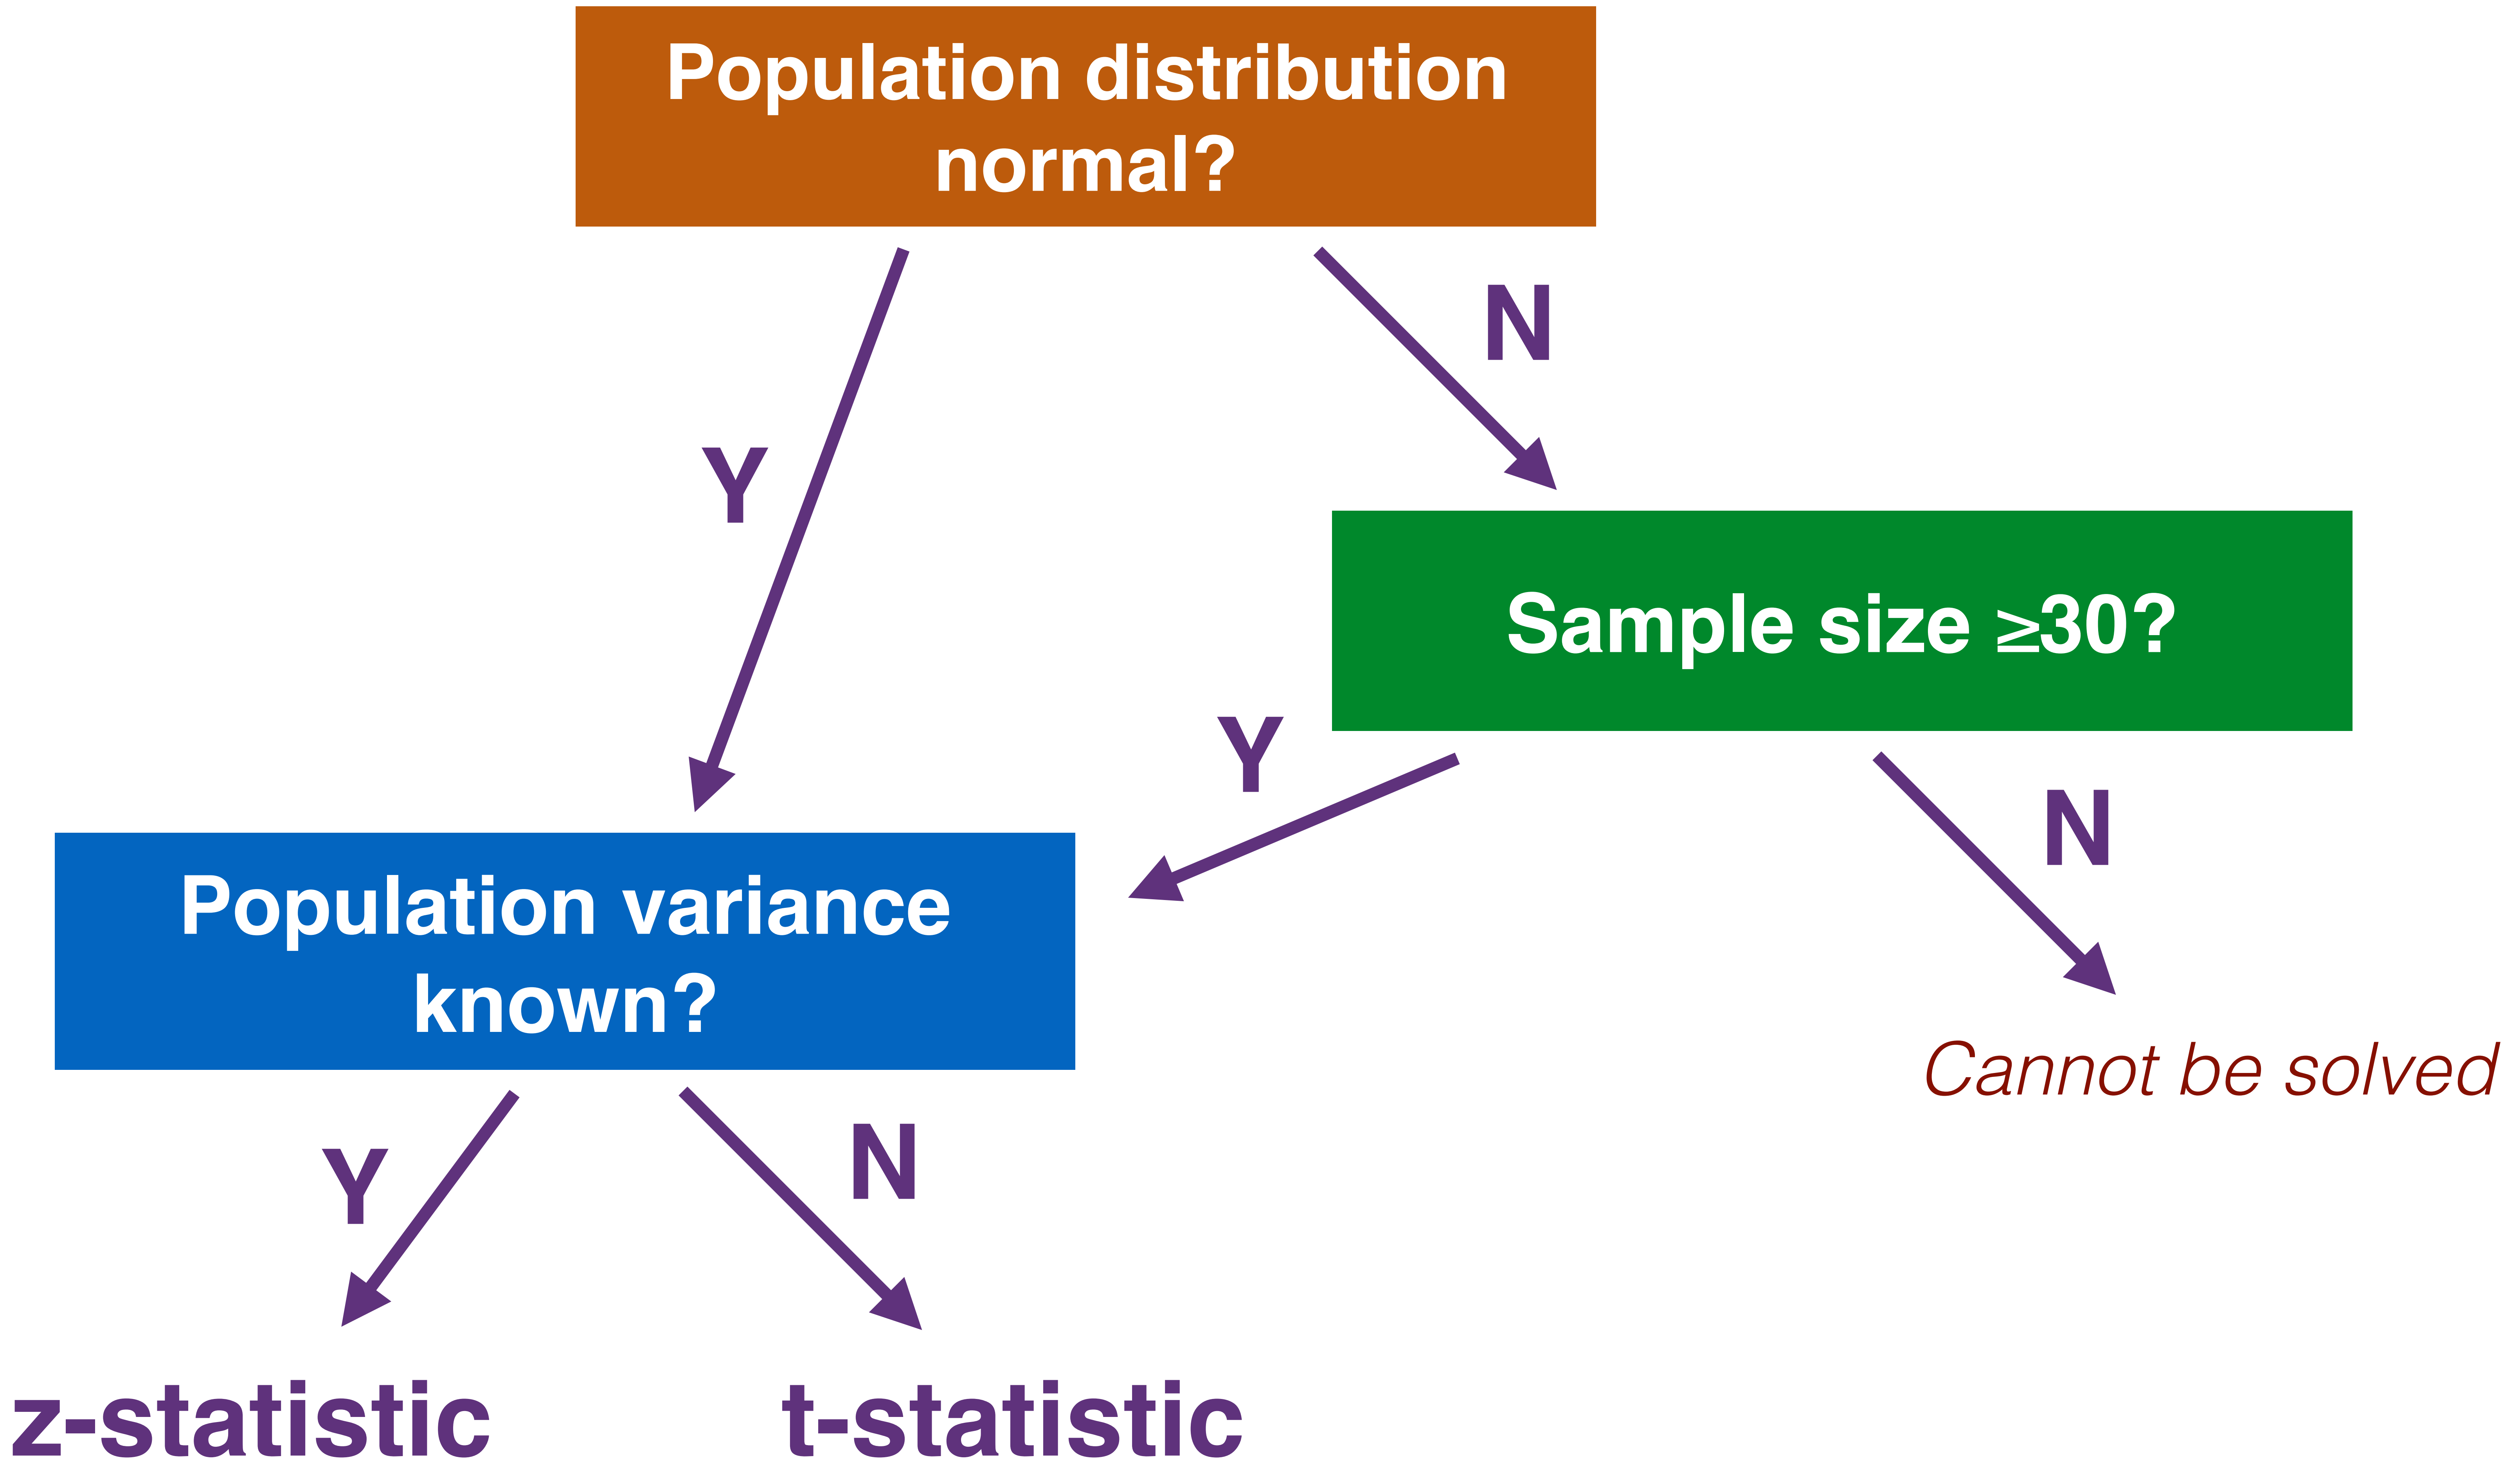
Hypothesis Testing

Hypothesis Tests Concerning the Mean

1. Single Mean
2. Differences Between Means

Criteria for Selecting Test Statistic



The battery life of a gadget is rated at a mean of 25 hours. The standard deviation is rated at 1 hour. The manufacturer guarantees this at 5% significance level.

The acceptance test for a batch of 10000 sets was performed by randomly selecting 30 sets from the batch. The mean battery life was found to be 24.5 hours. Should the batch be accepted?

μ: Mean battery life of batch

$\bar{x}$: Mean battery life of sample

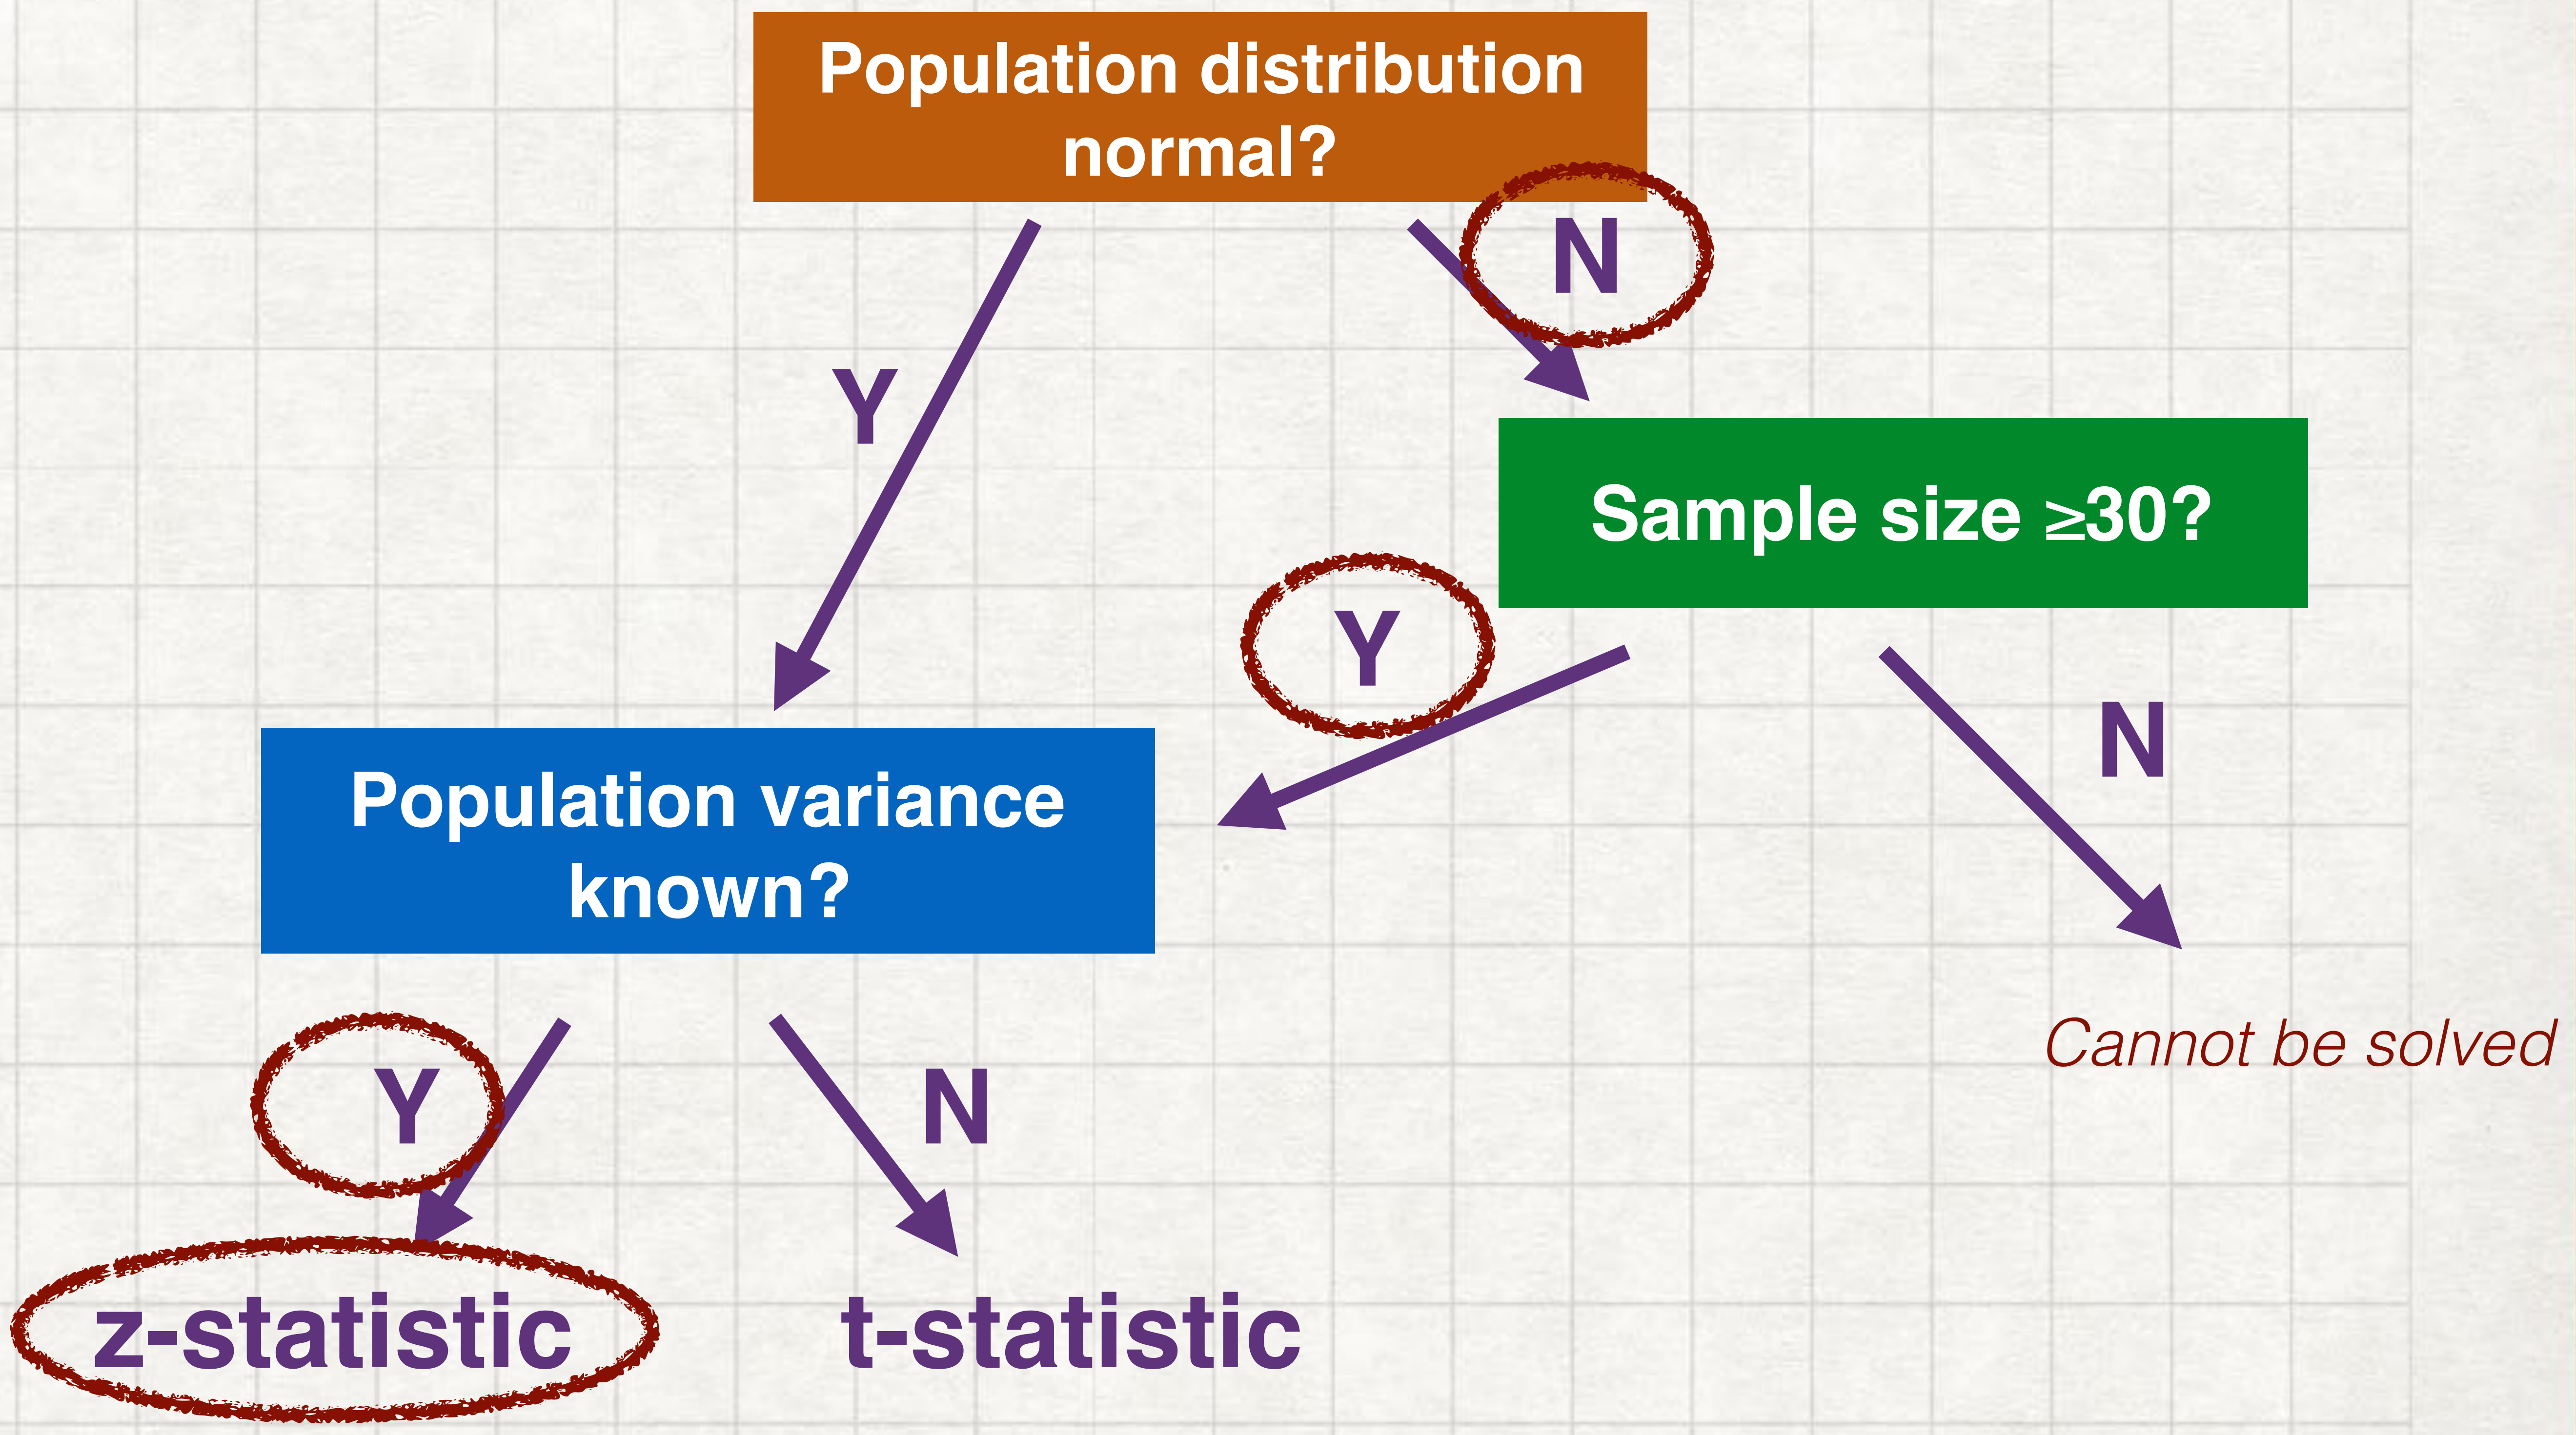
1. State the hypothesis

$H_0: \mu \geq 25$

$H_A: \mu < 25$

2. Select the test statistic

$$z = \frac{\bar{x} - 25}{\sigma / \sqrt{n}}$$



The battery life of a gadget is rated at a mean of 25 hours. The standard deviation is rated at 1 hour. The manufacturer guarantees this at 5%

Standard Normal Probabilities

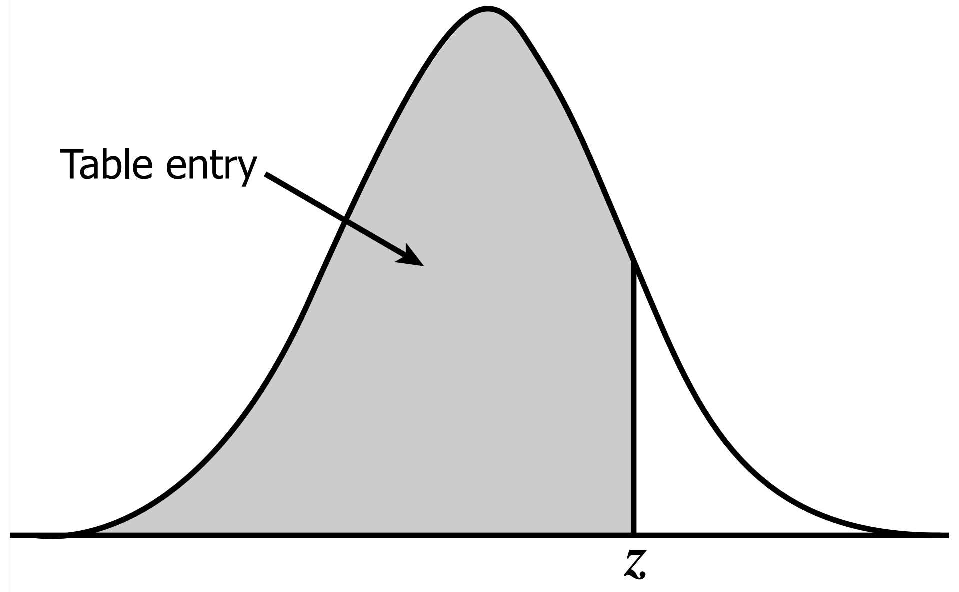


Table entry for z is the area under the standard normal curve to the left of z.

	Confidence Level										

The battery life of a gadget is rated at a mean of 25 hours. The standard deviation is rated at 1 hour. The manufacturer guarantees this at 5% significance level.
The acceptance test for a batch of 10000 sets was performed by randomly selecting 30 sets from the batch. The mean battery life was found to be 24.5 hours. Should the batch be accepted?

1. State the hypothesis

$H_0: \mu \geq 25$

$H_A: \mu < 25$

2. Select the test statistic

$$z = \frac{\bar{x} - 25}{\sigma / \sqrt{n}}$$

3. Specify significance level

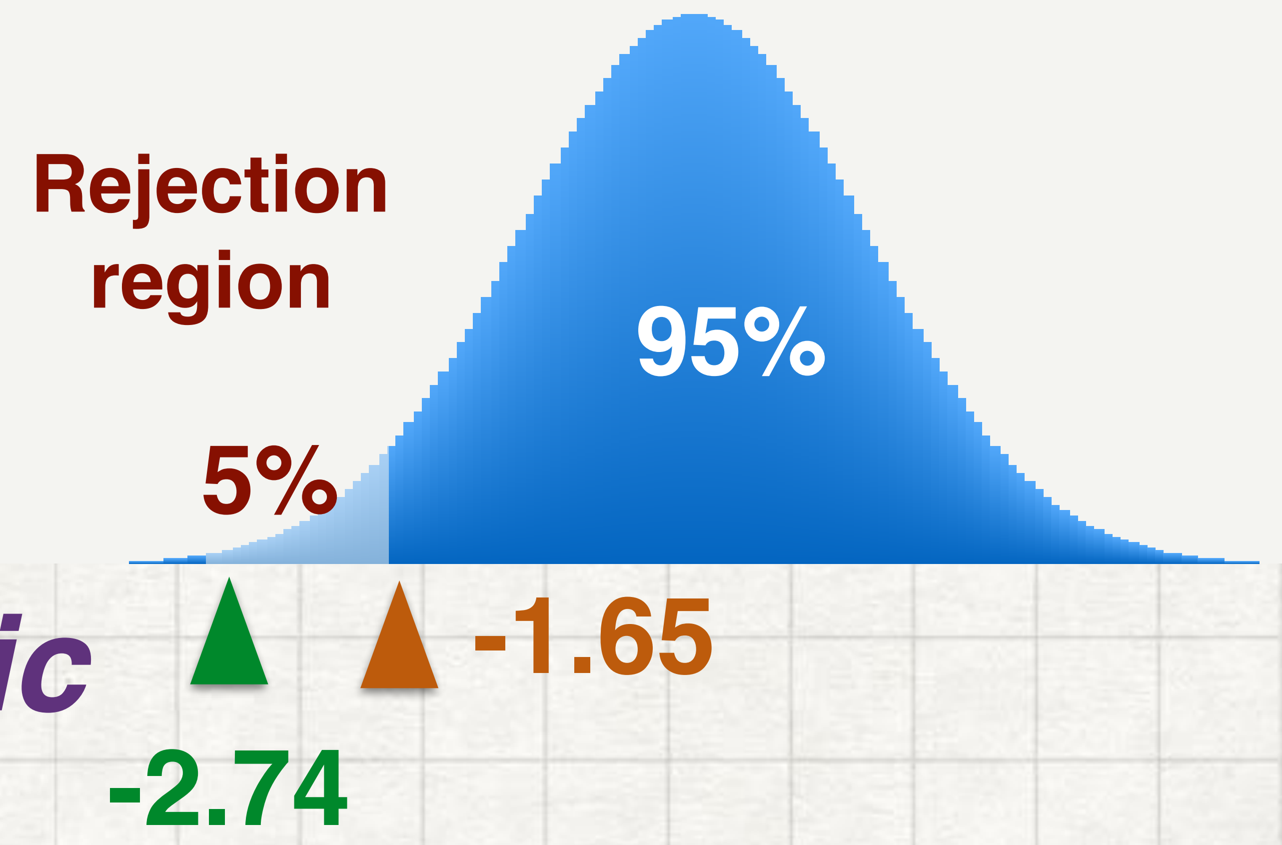
$\alpha = 5\%$

4. State decision rule

Reject H_0 if $z < -1.65$

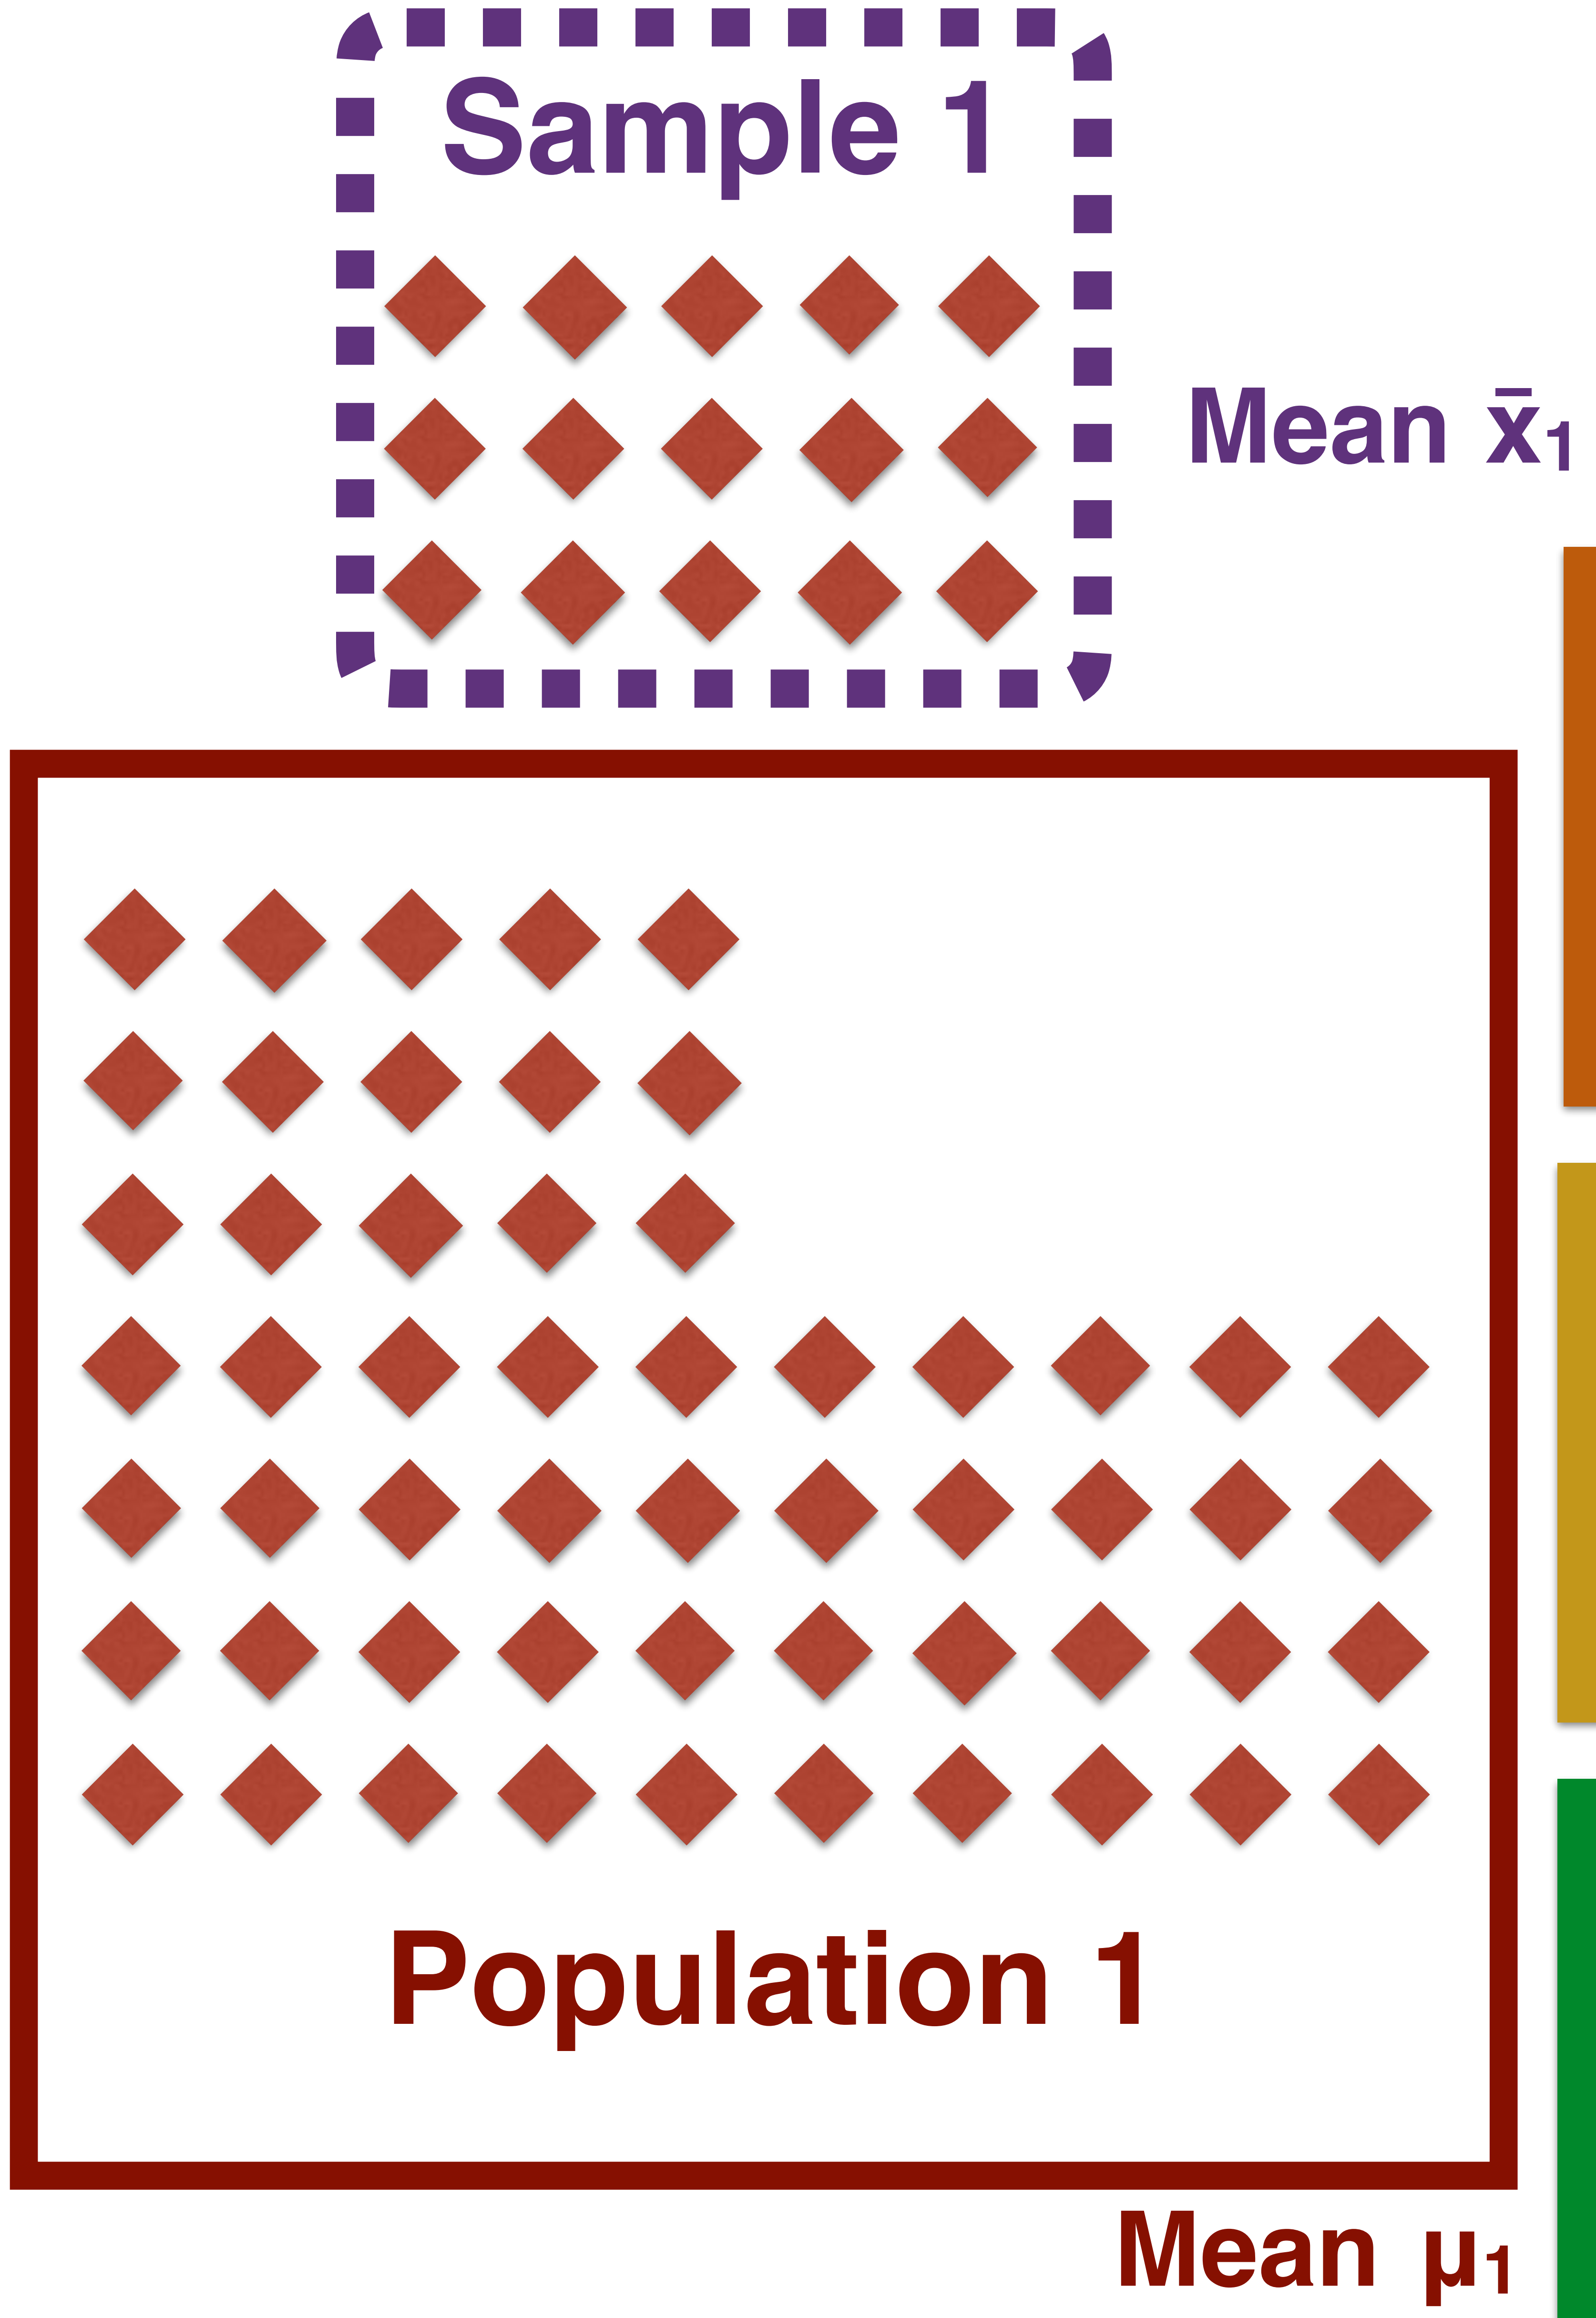
5. Calculate test statistic

$z = -2.74$



6. Statistical decision. Test statistic falls in rejection region. Reject H_0.

7. Economic decision. Batch does not meet specification. Reject the batch.



Concerned that means are not the same

$H_0: \mu_1 - \mu_2 = 0$ $H_A: \mu_1 - \mu_2 \neq 0$

Concerned that mean of pop1 is greater than pop2

$H_0: \mu_1 - \mu_2 \leq 0$ $H_A: \mu_1 - \mu_2 > 0$

Concerned that mean of pop1 is smaller than pop2

$H_0: \mu_1 - \mu_2 \geq 0$ $H_A: \mu_1 - \mu_2 < 0$

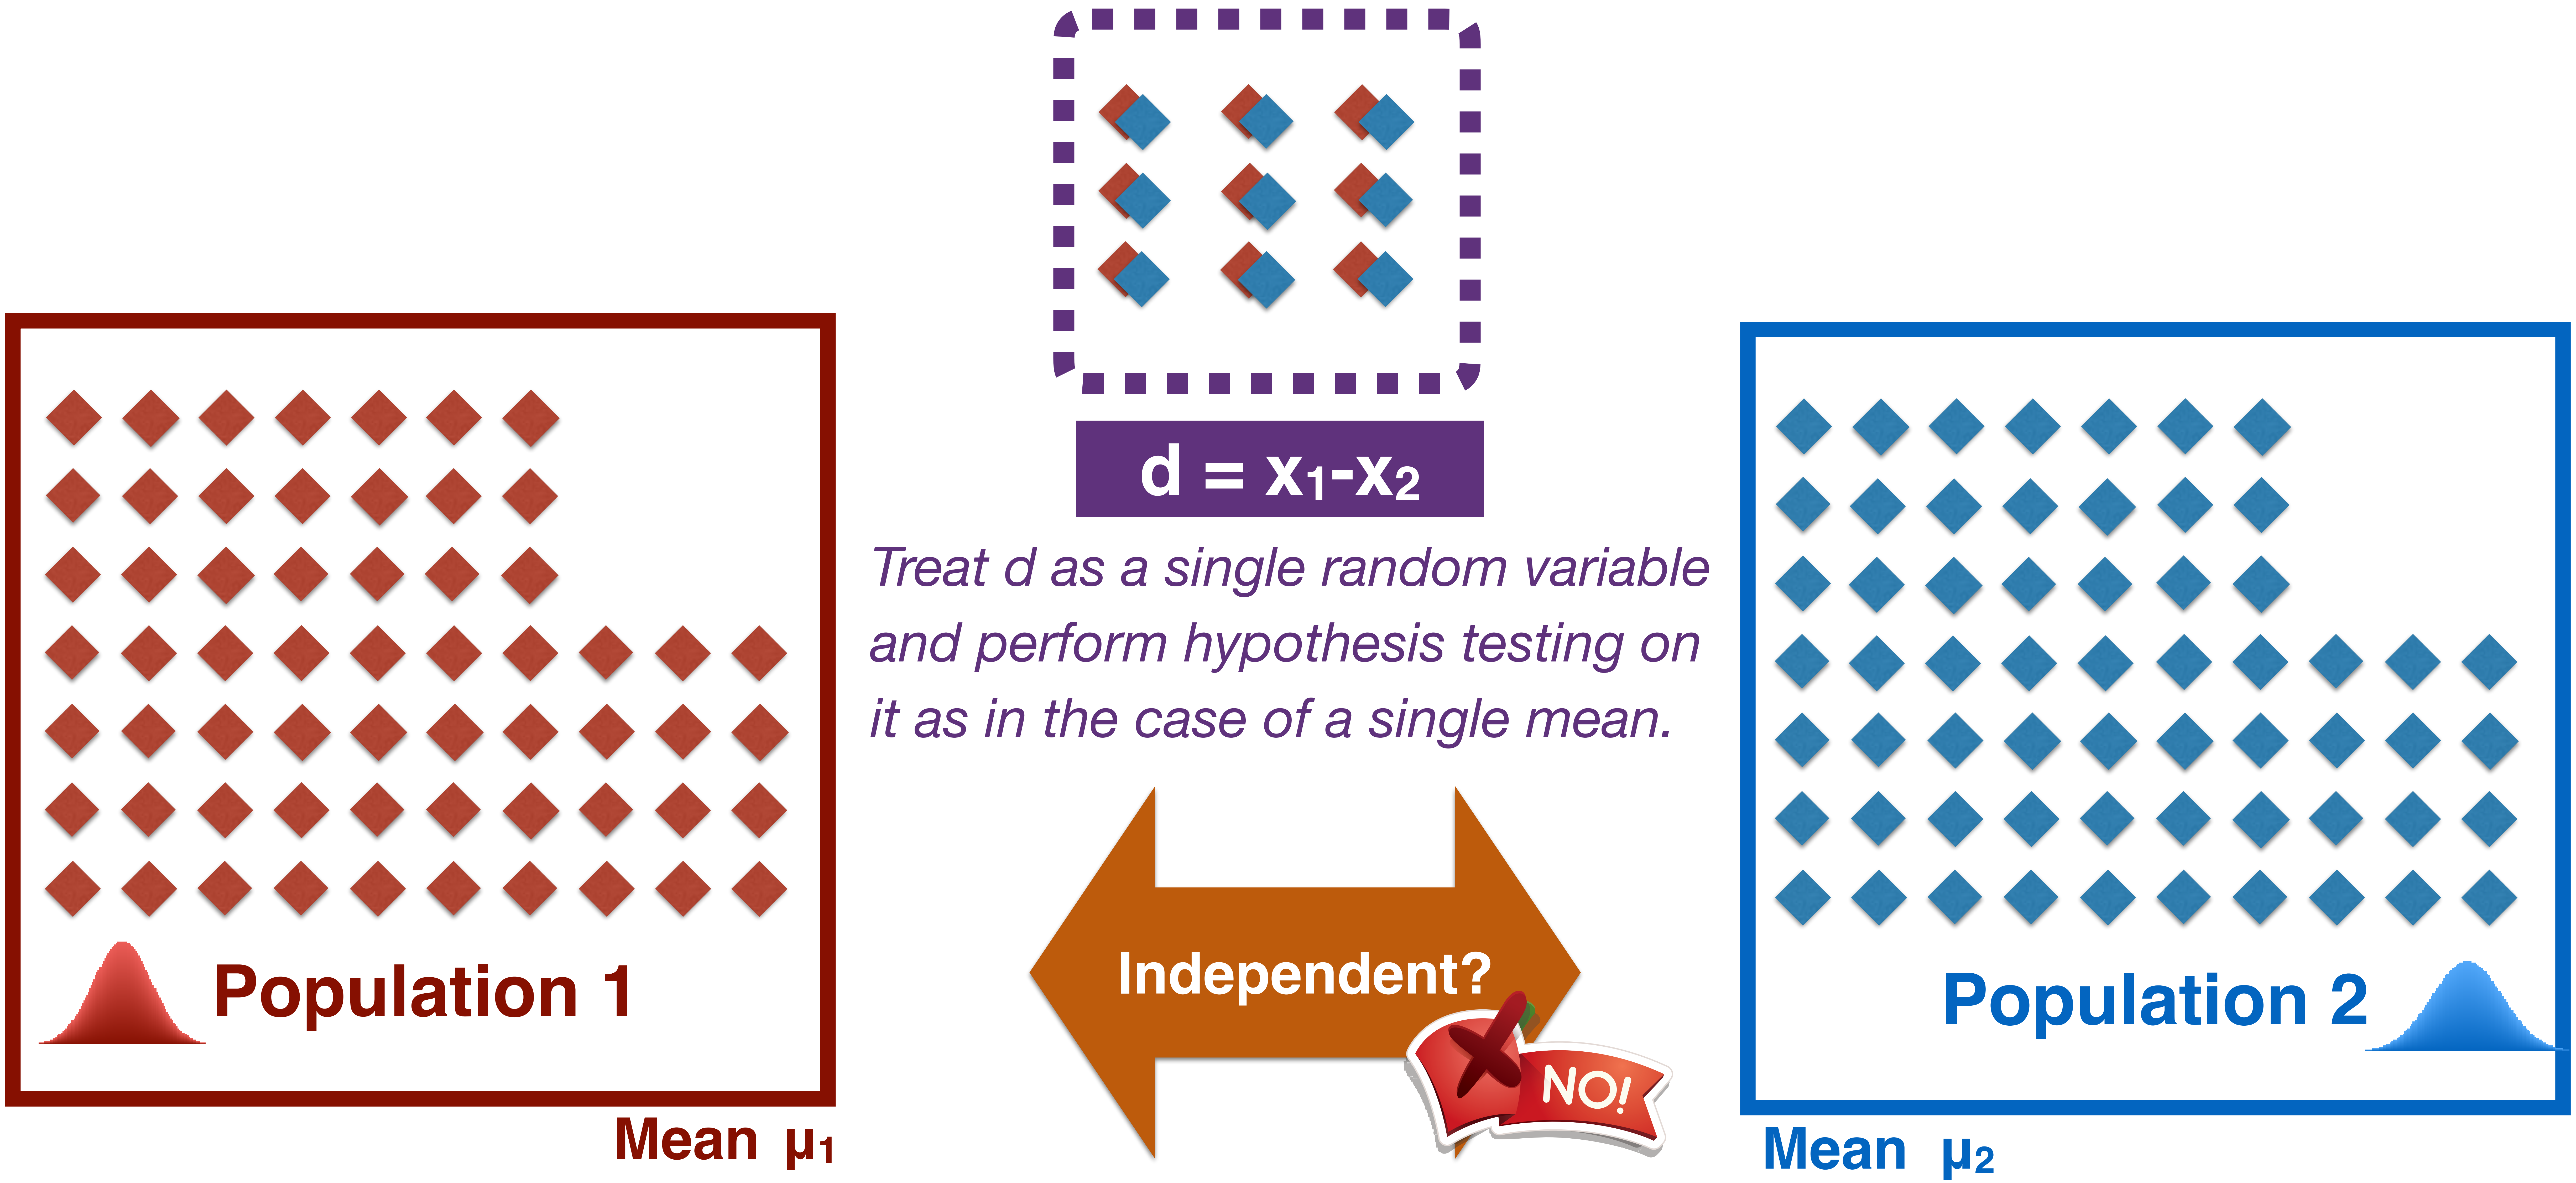
Paired Sample



Kent Boyle suspects that stocks tend to perform significantly differently after a stock split than after a stock consolidation. He picked a random sample of 31 stocks which had gone through a stock split and 31 stocks that had gone through a stock consolidation in the past 10 years and calculated their mean returns and standard deviations.

Assuming that the distribution of returns for both populations are normal, which approach to test the difference between the two means is the most appropriate?

Independent? YES

Different stocks
Different time periods

Variances equal? NO!

Outcomes from 2
unrelated events

Since the two populations are independent and their variances are not the same, we use the t-distribution with modified degrees of freedom, and non-pooled variance.

Kent Boyle suspects that stocks tend to perform significantly differently after a stock split than after a stock consolidation. He picked a random sample of 31 stocks which had gone through a stock split and 31 stocks that had gone through a stock consolidation in the past 10 years and calculated their mean returns and standard deviations.

Kent calculated the test statistic to be 1.672 and the degrees of freedom as 80. Perform a hypothesis test at 5% significance level to determine if Kent's suspicion is substantiated.

μ_1: Mean return of stocks that were split

μ_2: Mean return of stocks that were cons

Hypotheses

$H_0: \mu_1-\mu_2=0$ $H_A: \mu_1-\mu_2\neq 0$

Decision rule

Reject H_0 if $t<-1.99$ or $t>1.99$

Kent Boyle suspects that stocks tend to perform significantly differently after a stock split than after a stock consolidation. He picked a random sample of 31 stocks which had gone through a stock split and 31 stocks that had gone through a stock consolidation in the past 10 years and calculated their mean returns and standard deviations.

Kent calculated the test statistic to be 1.672 and the degrees of freedom as 80. Perform a hypothesis test at 5% significance level to determine if Kent's suspicion is substantiated.

μ_1: Mean return of stocks that were split

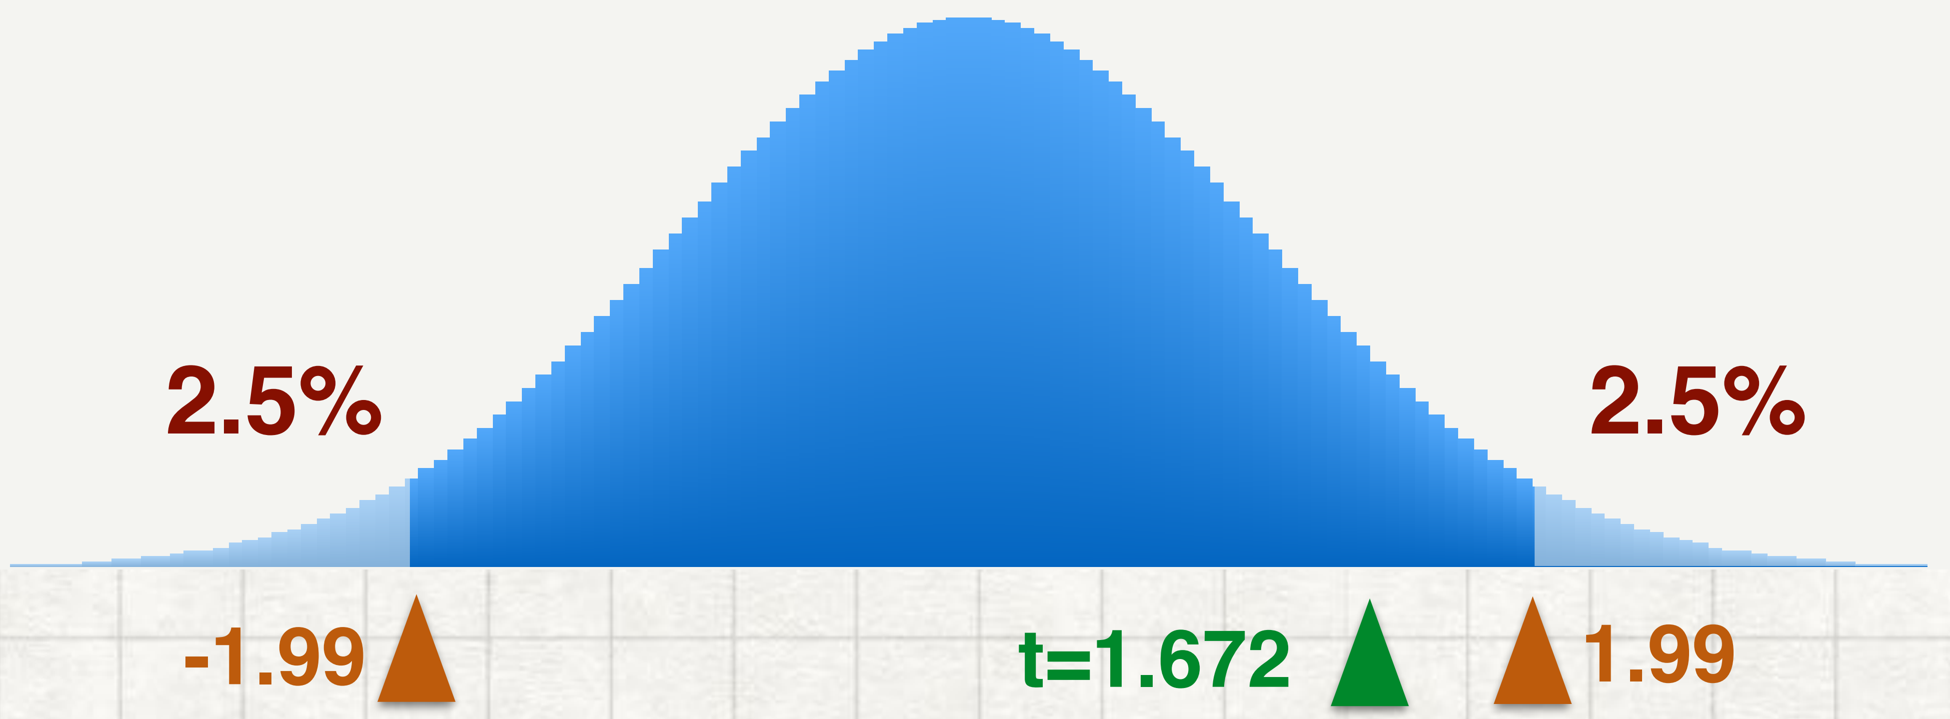
μ_2: Mean return of stocks that were consolidated

Hypotheses

$H_0: \mu_1-\mu_2=0$ $H_A: \mu_1-\mu_2\neq0$

Decision rule

Reject H_0 if $t<-1.99$ or $t>1.99$



Test Statistic

As given, $t=1.672$

Statistical Decision

Test statistic of 1.672 does NOT fall within rejection region.

Fail to reject H_0.

Kent Boyle's suspicion cannot be substantiated at 5% significance level

Hanna Rodrigues, CFA wants to investigate an observation that stocks tend to be more volatile in the first hour of trading than the last hour. To make a fair comparison, Hanna chooses the same random sample of 30 stocks for the analysis on both the first and last hour volatilities.

Which approach to testing the difference in mean volatilities between the first and the last hour is most appropriate?

Independent?

Same stocks for both samples

Since the two populations are NOT independent, the most appropriate approach is the paired comparisons test.

Hanna Rodrigues, CFA wants to investigate an observation that stocks tend to be more volatile in the first hour of trading than the last hour. To make a fair comparison, Hanna chooses the same random sample of 30 stocks for the analysis on both the first and last hour volatilities.

Upon analysing the sample, Hanna found that the mean of the difference in volatilities between the first and the last hours of trading is 2.5, with a standard deviation of 8.9. Perform a hypothesis test at 10% level of significan valid.

$d = x_1 - x_2$ *x_1: 1st hr volatility* *x_2: Last hr volatility*

Hypotheses

$H_0: \mu_d \leq 0$ $H_A: \mu_d > 0$

Decision rule

Reject H_0 if $t > 1.311$

Hanna Rodrigues, CFA wants to investigate an observation that stocks tend to be more volatile in the first hour of trading than the last hour. To make a fair comparison, Hanna chooses the same random sample of 30 stocks for the analysis on both the first and last hour volatilities.

Upon analysing the sample, Hanna found that the mean of the difference in volatilities between the first and the last hours of trading is 2.5, with a standard deviation of 8.9. Perform a hypothesis test at 10% level of significance to determine if the observation is valid.

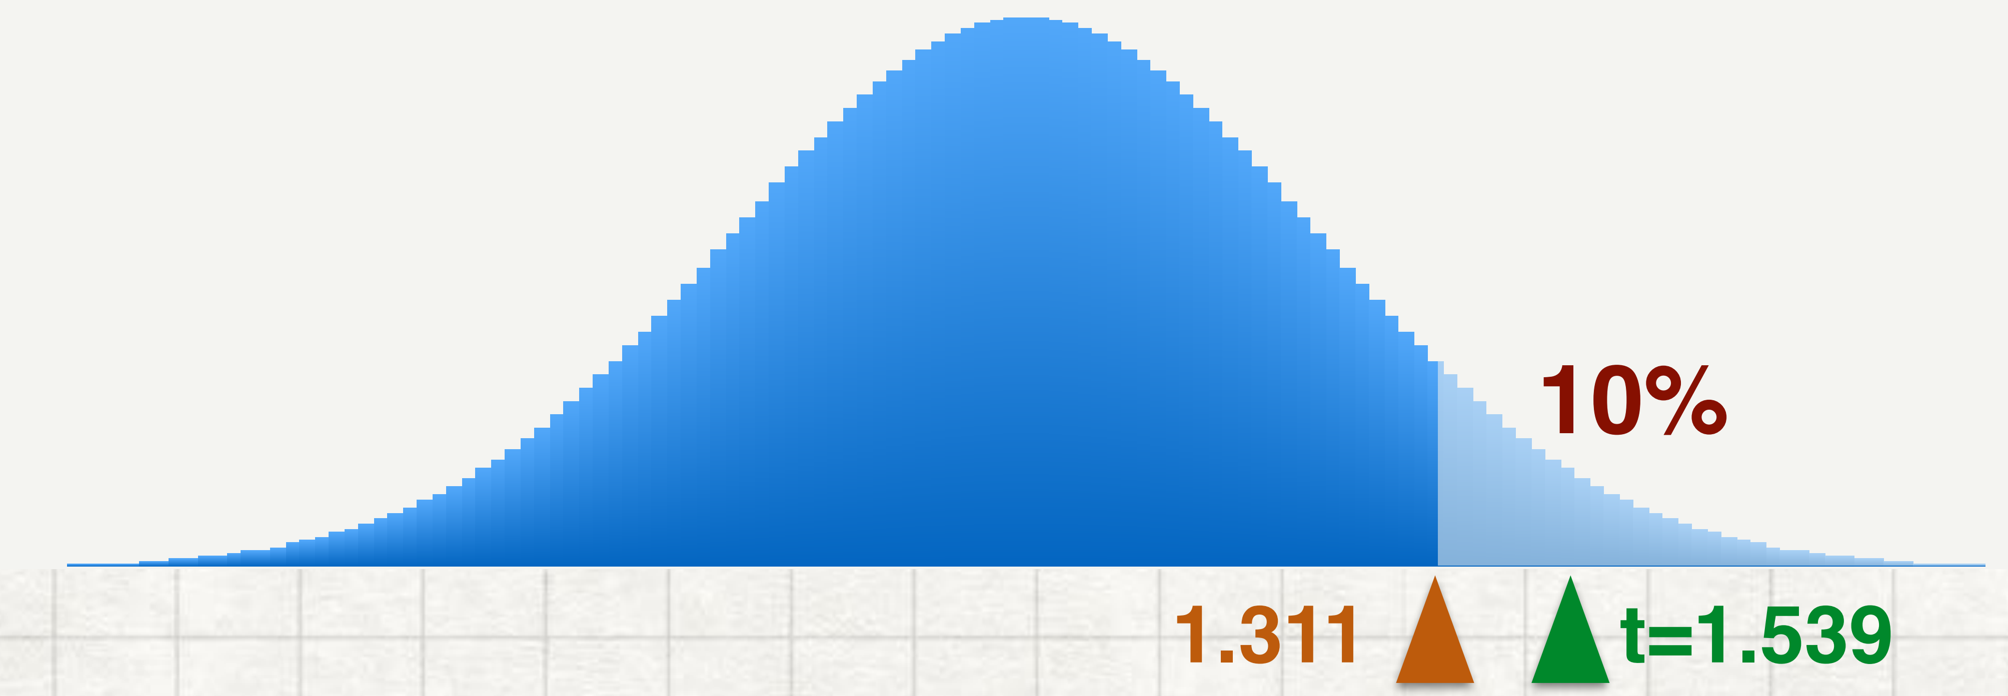
$d = x_1 - x_2$

Hypotheses

$H_0: \mu_d \leq 0$ $H_A: \mu_d > 0$

Decision rule

Reject H_0 if $t > 1.311$



Test Statistic

$$t = \frac{2.5-0}{8.9/\sqrt{30}} = 1.539$$

Statistical Decision

Test statistic of 1.539 falls within rejection region.

Reject H_0.

Volatility of stocks is greater in 1st hour than in last hour at 10% significance level

Single Mean

Difference between Means
